

# UPGMA implementation

Usman Roshan

# Representing phylogenies

- We use three lists to represent rooted binary trees: parent, left child, and right child.
- The node id is the index in the array.
- For leaves the left and right child is set to -1.
- If a node has no parent then its value in the list is set to -1.

# Representing phylogenies

	0	1	2	3	4	5	6
P:	4	4	5	5	6	6	-1

L:	-1	-1	-1	-1	0	2	4
----	----	----	----	----	---	---	---

R:	-1	-1	-1	-1	1	3	5
----	----	----	----	----	---	---	---

# Representing phylogenies

- Write the P, L, and R lists for the phylogeny below.

# UPGMA pseudocode

- Read distance matrix  $D$  from file and make copy of it called  $d$ .
- Initialize  $P$ ,  $L$ , and  $R$  lists
- While ( $\text{nodes\_to\_do} > 1$ ):
  - Find closest pair in distance matrix  $d$
  - Add new node in tree
  - Update distance matrix
  - $\text{nodes\_to\_do} = \text{nodes\_to\_do} - 1$

# UPGMA pseudocode

- Initialization:
  - D has dimensions  $n \times n$  where  $n$  is the number of sequences (leaves)
  - The final tree will have  $2n + 1$  nodes
  - We set  $d$  to be of dimension  $2n + 1$
- Find closest pair in  $d$ :
  - Returns indices  $i$  and  $j$  that are closest
  - Ignore entries that are non-positive
- Add new node in tree
  - Parameters are  $P$ ,  $L$ ,  $R$ ,  $\text{new\_node\_id}$  and indices  $i$  and  $j$  from above function

# UPGMA pseudocode

- Update distance matrix  $d$ 
  - Calculate distances from new node to nodes that have parent set to -1
  - Set row and column of nodes  $i$  and  $j$  (that were returned by `find_closest_pair`) to -1
