

## Lecture 2

# Motion along a straight line

(HR&W, Chapter 2)

Physics 105; Summer 2006

## Motion along a straight line

- Motion
- Position and Displacement
- Average velocity and average speed
- Instantaneous velocity and speed
- Acceleration
- Constant acceleration: A special case
- Free fall acceleration

## Motion along a straight line

- this is the simplest type of motion
- it lays the groundwork for more complex motion

### Kinematic variables in one dimension

Position	$x(t)$ meters
Velocity	$v(t)$ meters/second
Acceleration	$a(t)$ meters/second <sup>2</sup>

All depend on time

All are vectors: have direction and magnitude.

## Motion

- Everything moves!
- Classification and comparison of motion  
⇒ **kinematics**
- Simplification
  - Motion along straight line
  - Forces cause changes in motion
  - Moving object is a particle or moves like a particle

## One Dimensional Position: $x(t)$

Position is a **vector** quantity.

Position has both a **direction** and **magnitude**.

Position has units of [Length]: *meters*.

Must define:

- >  $x = 0$  some position (Origin)
- > positive direction for  $x$

## Displacement Along a Straight Line

Must define:  $t = 0$

Displacement:  $\Delta x = x_2 - x_1$

$$x_1 = 3 \text{ m}$$

$$x_2 = -2 \text{ m}$$

$$\Delta x = -5 \text{ m}$$

Displacement is a change of position in time.

It is a **vector** quantity.

It has both a **direction** and **magnitude**.

It has units of [Length]: *meters*.

## Displacement Along a Straight Line

$t=0$ ; (start the clock)       $x = 0$ ; (origin)

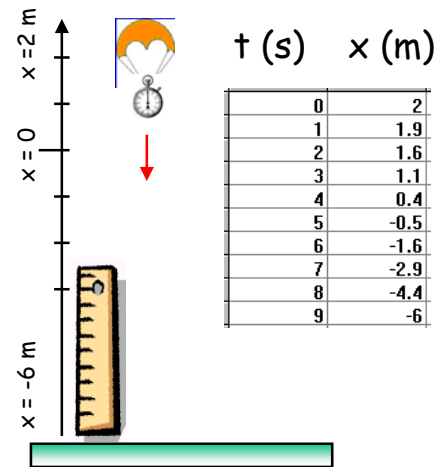

$x(t=0)$  does not have to be 0

Straight line can be oriented

Horizontal, vertical, or at some angle

## Displacement Along a Straight Line

Motion with respect to the origin !

# Displacement

Displacement in time:

$$\Delta t = t_2 - t_1$$

Displacement in Space:

$$\Delta x = x(t_2) - x(t_1)$$

or

$$\Delta x = x_2 - x_1$$

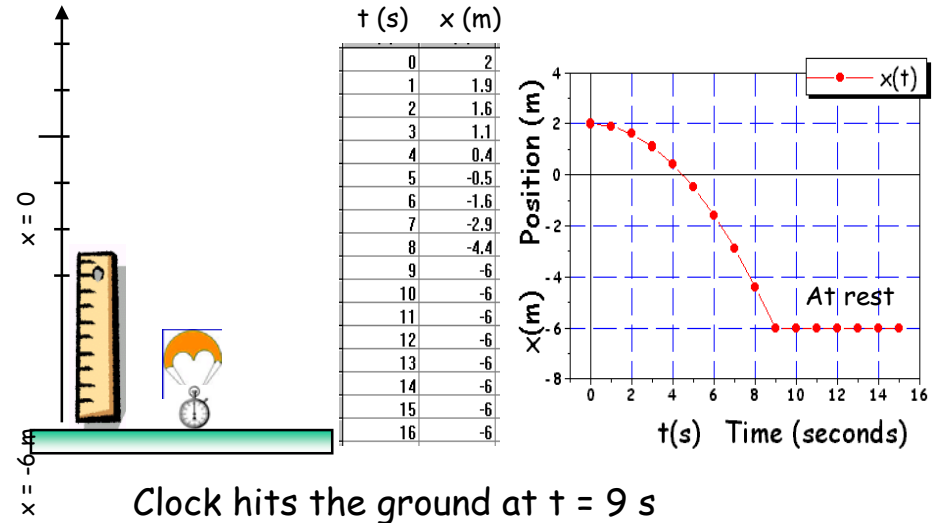

Avg:

$$x(t_2) - x(t_1)$$

is negative

# Displacement Along a Straight Line

Clock hits the ground at t = 9 s

# Velocity

Average velocity

$$v_{avg} = \frac{\Delta x}{\Delta t} = \frac{x_2 - x_1}{t_2 - t_1} = -8/9 \text{ m/s} \approx -0.9 \text{ m/s}$$

Average speed

$$s_{avg} = \frac{\text{total distance}}{\Delta t} = 8/9 \text{ m/s} \approx 0.9 \text{ m/s}$$

Instantaneous velocity

$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}$$

Velocity is the rate of change of position

# Velocity is a vector !

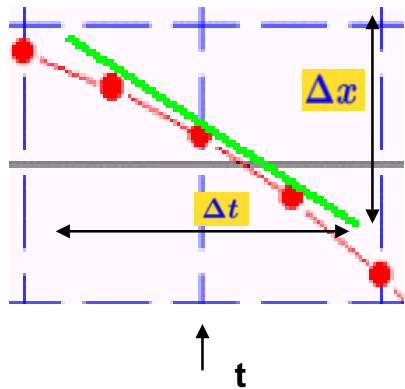

Velocity has direction !

Velocity can change with time

# Instantaneous Velocity

Consider smaller time intervals:

Instantaneous velocity  $v(t)$  is the slope of the tangent line to  $x(t)$

$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}$$

changes with time !

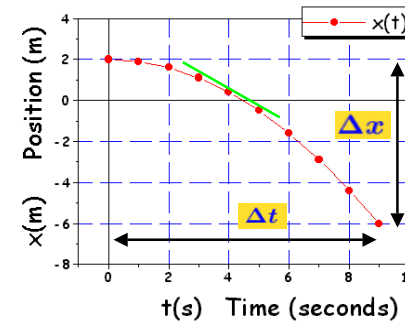

$v(t)$  is a function of time !

# Velocity

$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}$$

Example of negative  $v$

Velocity is positive in the same direction as  $x$  is positive

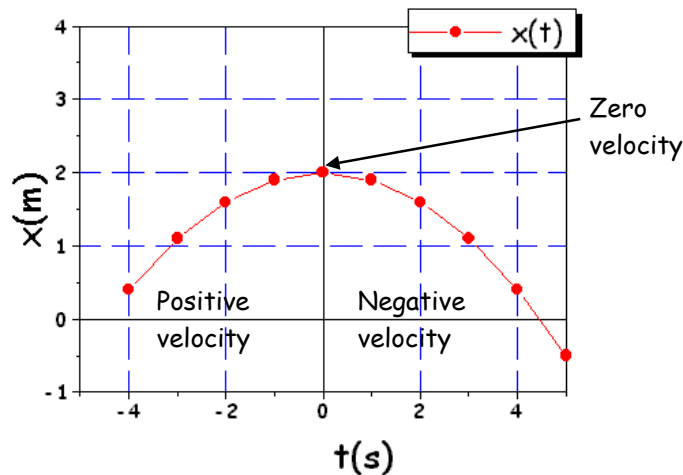

Example of a constant acceleration:

Velocity is positive in the same direction as  $x$  is positive

$$v(t) = at$$

$v(t)$  is a straight line

# Sign of velocity

$v(t)$  is a function of time !

# Velocity

HR&W

"moving armadillo"

- Average velocity

$$v_{avg} = \frac{\Delta x}{\Delta t} = \frac{x_2 - x_1}{t_2 - t_1} = 6/3 \text{ m/s}$$

- Average speed

$$s_{avg} = \frac{\text{total distance}}{\Delta t} = 6/3 \text{ m/s}$$

- Instantaneous velocity

$$v = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}$$

# Acceleration

- Average acceleration

$$a_{\text{avg}} = \frac{v_2 - v_1}{t_2 - t_1} = \frac{\Delta v}{\Delta t}$$

- Instantaneous acceleration

$$a = \frac{dv}{dt}$$

- Constant acceleration

$$v = v_0 + at$$

$$x - x_0 = v_0 t + \frac{1}{2} at^2$$

(a)

(b)

(c)

# Constant Acceleration

( $a > 0$ )

$$v(t) = v_0 + at;$$

$$x(t) - x_0 = v_0 t + at^2/2$$

$$x(t) - x_0 = (v(t)^2 - v_0^2)/2a$$

(a)

(b)

(c)

# Kinematic Variables

Position is a function of time:  $x = x(t)$

Velocity is the rate of change of the position

Acceleration is the rate of change of the velocity

$$v(t) = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}$$

$$a(t) = \lim_{\Delta t \rightarrow 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt}$$

# What does zero mean?

- $t = 0$  beginning of the process
- $x = 0$  is arbitrary; can set where you want it
- $x_0 = x(t=0)$ ; position at  $t=0$ ; do not mix with the origin

- $v(t) = 0$   $x$  does not change  $x(t) - x_0 = 0$
- $v_0 = 0$   $v(t) = at$ ;  $x(t) - x_0 = at^2/2$
- $a = 0$   $v(t) = v_0$ ;  $x(t) - x_0 = v_0 t$

- 
- $a \neq 0$   $v(t) = v_0 + at$ ;  $x(t) - x_0 = v_0 t + at^2/2$
  - help:  $t = (v - v_0)/a$   $x - x_0 = \frac{1}{2}(v^2 - v_0^2)/a$
  - $a = (v - v_0)/t$   $x - x_0 = \frac{1}{2}(v + v_0)t$

- Acceleration and velocity are positive in the same direction as displacement is positive

# Free Fall

Most important case of constant acceleration: Free fall

$$a = -g \quad \text{where } g = 9.8 \text{ m/s}^2$$

(defining "up" as the positive direction)

$Y=0$

# Gravitation is universal

Gravitational acceleration does not depend on the nature of the material or the mass of the object.

## Three cases of free fall

$$x(t) = x_0 + v_0 t + \frac{1}{2}(-g)t^2$$

$$v(t) = v_0 + (-g)t$$

$v_0 = 0$

$v_0 < 0$

$v_0 > 0$

## Sample Problem II-2

p. 18

An elevator is initially stationary, then moves upward (which we take the positive direction of  $x$ ), and then stops. Plot  $V$  as a function of time.

(a)  $x(t)$  curve for an upward moving elevator cab

(b)  $v(t)$  curve for the cab. Note  $v = dx/dt!$

(c)  $a(t)$  curve for the cab. Note  $a = dv/dt!$

# Conclusions: Motion along a straight line

- the simplest type of motion
- the groundwork for more complex motion

### Kinematical variables in one dimension

Position:  $x(t)$  meters  
 Velocity:  $v(t)$  meters/second  
 Acceleration:  $a(t)$  meters/second <sup>2</sup>

All depend on time

All are **vectors**: have direction and magnitude.

**TABLE 2-1 Equations for Motion with Constant Acceleration<sup>a</sup>**

Equation Number	Equation	Missing Quantity
2-11	$v = v_0 + at$	$x - x_0$
2-15	$x - x_0 = v_0t + \frac{1}{2}at^2$	$v$
2-16	$v^2 = v_0^2 + 2a(x - x_0)$	$t$
2-17	$x - x_0 = \frac{1}{2}(v_0 + v)t$	$a$
2-18	$x - x_0 = vt - \frac{1}{2}at^2$	$v_0$

<sup>a</sup> Make sure that the **acceleration** is indeed constant before using the equations in this table.

## Next Lecture: Motion in 2D and 3D + Vectors

### One dimension (1D)

Position:  $x(t)$  m  
 Velocity:  $v(t)$  m/s  
 Acceleration:  $a(t)$  m/s<sup>2</sup>

### Three dimension (2D)

Position:  $\vec{r}(t)$  m  
 Velocity:  $\vec{v}(t)$  m/s  
 Acceleration:  $\vec{a}(t)$  m/s<sup>2</sup>

All are **vectors**: have direction and magnitude.

## Lecture QZ2

2. A stone is dropped from the height of 150 ft with no initial velocity. What is the rock's **speed** after the first 2 seconds. (Neglect the air resistance).

*Hint:* The free fall acceleration  $g = 9.8 \text{ m/s}^2$   
 150 ft  $\rightarrow$  ? m
