Gravitation

HW&R

http://web.njit.edu/~sirenko/

The Andromeda galaxy. Located 2.3 × 10^6 light-years from us

- On Earth: the Earth gravitation dominates
  \( F = mg \)

- In the Solar System: attraction to the Sun is the main effect

- In the Galaxy (Milky Way): Attraction to the center of the Galaxy determines everything.

- At the edge of the Universe: the conceptual problems begin ...
  Accelerating expansion of the visible Universe is known since 1998. From that time this problem became one of the frontiers of the modern Physics

Newton's Law of Gravitation (known since 1665)

\[
F = G \frac{m_1 m_2}{r^2}
\]

\[ G = 6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2 \]

Measuring the Gravitational constant G using the Cavendish method

\[
G = 6.67 \times 10^{-11} \text{ N} \cdot \text{m}^2/\text{kg}^2
\]
Newton’s Law of Gravitation

\[ F = G \frac{m_1 m_2}{r^2} \]

A uniform spherical shell of matter attracts a particle that is outside the shell as if all the shell’s mass is concentrated at its center!

Solid sphere is a combination of spherical shells:

Gravitation Near Earth’s Surface

Gravitational acceleration:

\[ F = G \frac{Mm}{r^2} = ma_g \Rightarrow a_g = \frac{GM}{r^2} \]

1. Earth is not uniform.
2. Earth is not a sphere.
3. Earth is rotating.

Mean Earth surface (0 km, 9.83 m/s²), Mt. Everest (8.8 km, 9.80 m/s²), highest manned balloon (36.6 km, 9.71 m/s²), Space Shuttle orbit (400 km, 8.70 m/s²), and communications satellite (35,700 km, 0.225 m/s²)
**Gravitation inside the Earth “Alice in Wonderland”**

Outside the Earth (r > R)

\[ F = \frac{G m_1 m_2}{r^2} \]

\[ a_g \approx g = \frac{9.8}{m/s^2} \]

Gravitational Train “Alice”

(a) Will this train move at all?
(b) What is the total force on the train in the middle of the tunnel?
(c) Where will the train stop?
LA or in the middle of the tunnel
(c) What is the speed of the train in the middle of the tunnel?

Answers:
(a) \( v \approx 6000 \text{ m/s} \)
(b) \( v \approx 600 \text{ m/s} \)
(c) \( v \approx 60 \text{ m/s} \)
(d) \( v \approx 6 \text{ m/s} \)
(e) \( v \approx 0 \)

**Planets and Satellites: Kepler’s Laws**

**THE LAW OF ORBITS:** All planets move in elliptical orbits, with the Sun at one focus.

A planet of mass \( m \) moving in an elliptical orbit around the Sun. The Sun, of mass \( M \), is at one focus \( F \) of the ellipse. The other focus is \( F' \), which is located in empty space. Each focus is a distance \( e a \) from the ellipse's center, with \( e \) being the eccentricity of the ellipse. The semimajor axis \( a \) of the ellipse, the perihelion (nearest the Sun) distance \( R_p \), and the aphelion (farthest from the Sun) distance \( R_a \) are also shown.
Planets and Satellites: Kepler's Laws

**The Law of Areas:** A line that connects a planet to the Sun sweeps out equal areas in the plane of the planet's orbit in equal times; that is, the rate $\frac{dA}{dt}$ at which it sweeps out area $A$ is constant.

In time $\Delta t$, the line connecting the planet to the Sun (of mass $M$) sweeps through an angle $\Delta \theta$, sweeping out an area $\Delta A$ (shaded).

Potential Energy:

$\Delta U$ between $r_1$ and $r_2$ is the work done by the Gravitation Force during the move from $r_1$ to $r_2$:

$$ F = \frac{GMm_1m_2}{r^2} $$

Reference point $r = 0$

$$ U_1 = -\frac{GMm}{r_1} $$

$$ U_2 = -\frac{GMm}{r_2} $$

$U = 0$; at infinity! (far away)

---

**The Law of Periods:** The square of the period of any planet is proportional to the cube of the semimajor axis of its orbit.

$$ T^2 = \frac{4\pi^2}{GM}r^3 $$

$U = 0$; at infinity! (far away)
Potential Energy:

Is it $\Delta U = mgh$ or $U = -\frac{GMm}{r}$, anyway?

It is the same thing, just different zero levels.

$U = -\frac{GMm}{r}$ is more universal (always correct)

$\Delta U = mgh$ works for $h \ll r$, zero at the Earth surface

$U = -\frac{GMm}{r}$ always works, zero at $\infty$

$\Delta U = \frac{GMm}{r} - \frac{GMm}{(r+h)} = \frac{GMm(r+h-r)}{r\cdot(r+h)} = mh\cdot\frac{GM}{r\cdot(r+h)} \approx mgh$

Escape Speed:

From energy conservation:

$E_1 = mv^2/2 - \frac{GMm}{R}$

$E_2 = 0$ (velocity is small)

$v^2 = 2GM/R = 2gR$

$v = (2GM/R)^{1/2} \approx 11,200 \text{ m/s}$

First Satellite Speed:

“Newton’s cannon” in 1687 in “Principia Mathematica”

$v_{\text{satellite}} \approx (gR)^{1/2}$

$v_{\text{satellite}} \approx 8,000 \text{ m/s}$

$g \approx 8.70 \text{ m/s}^2$

An object in orbit is weightless not because 'it is beyond the earth's gravity' but because it is in 'free-fall' - just like a skydiver.
Potential and Kinetic Energy

Potential Energy

\[ U = -\frac{GMm}{r} \]

Kinetic Energy for the orbital motion

\[ F = G\frac{Mm}{r^2} = \frac{mv^2}{r} \quad \Rightarrow \quad K = \frac{1}{2}mv^2 = \frac{GMm}{2r} \]

Total Energy

\[ E = K + U = \frac{GMm}{2r} - \frac{GMm}{r} = -\frac{GMm}{2r} \]
